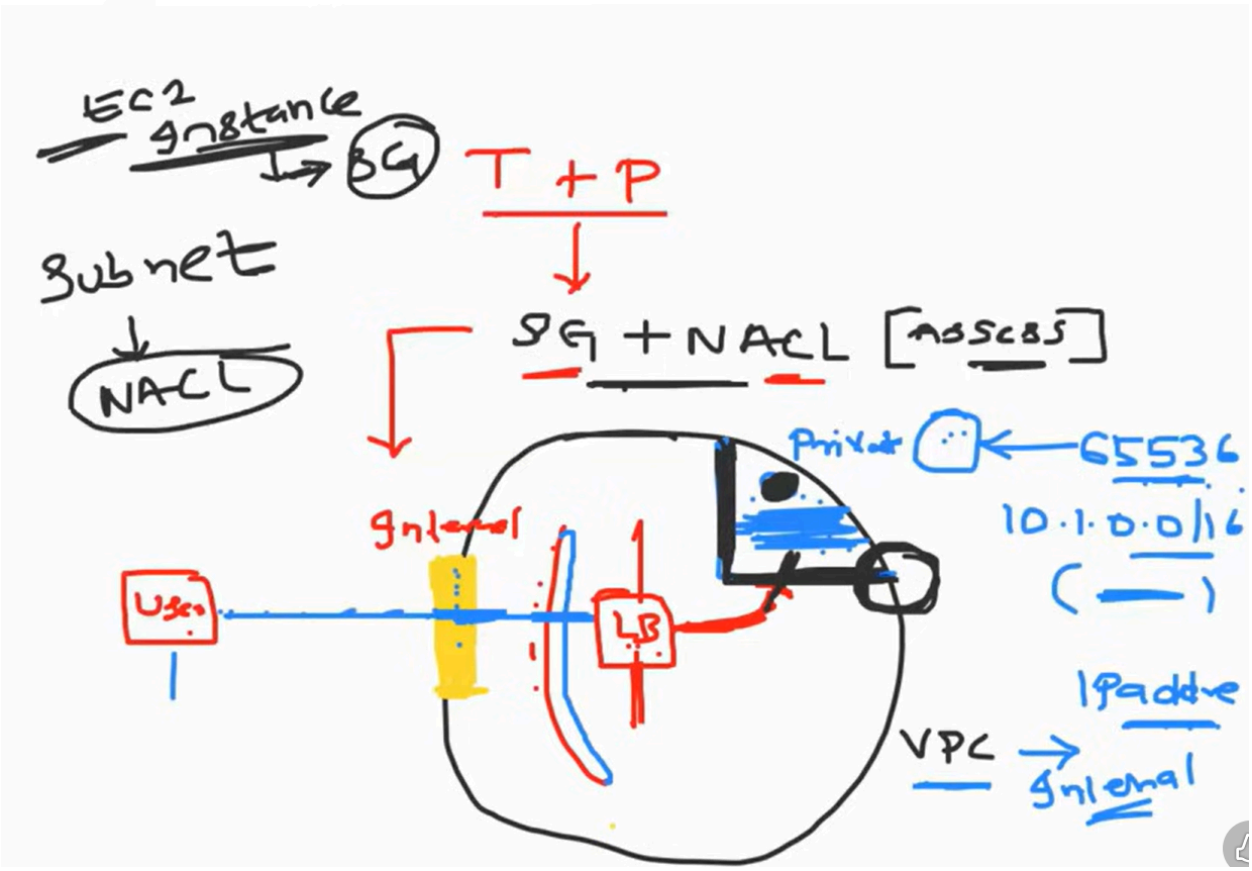
DAY 5 VPC PART 2

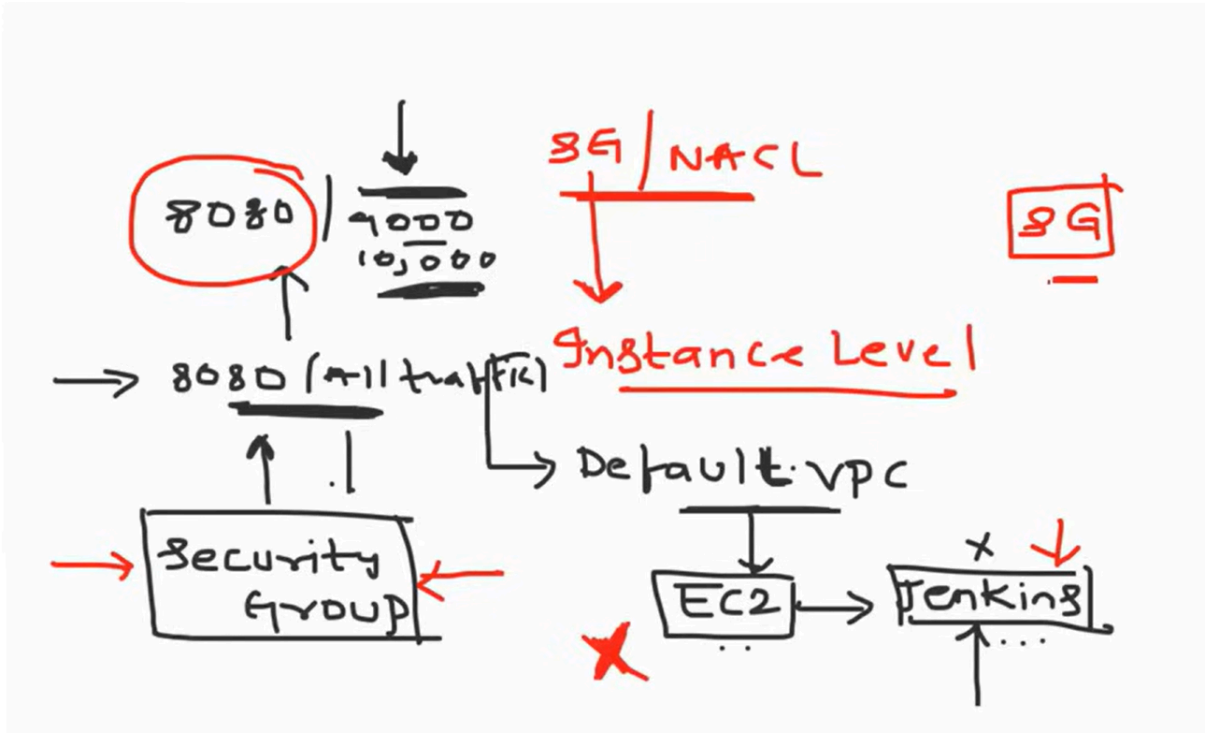
SECURITY GROUP



If we add a security group at the private subnet level, we can do it by using NACL.
We can also bypass this and add the security at the instance level inside the private subnet as an application owner, then it will be called a security group.

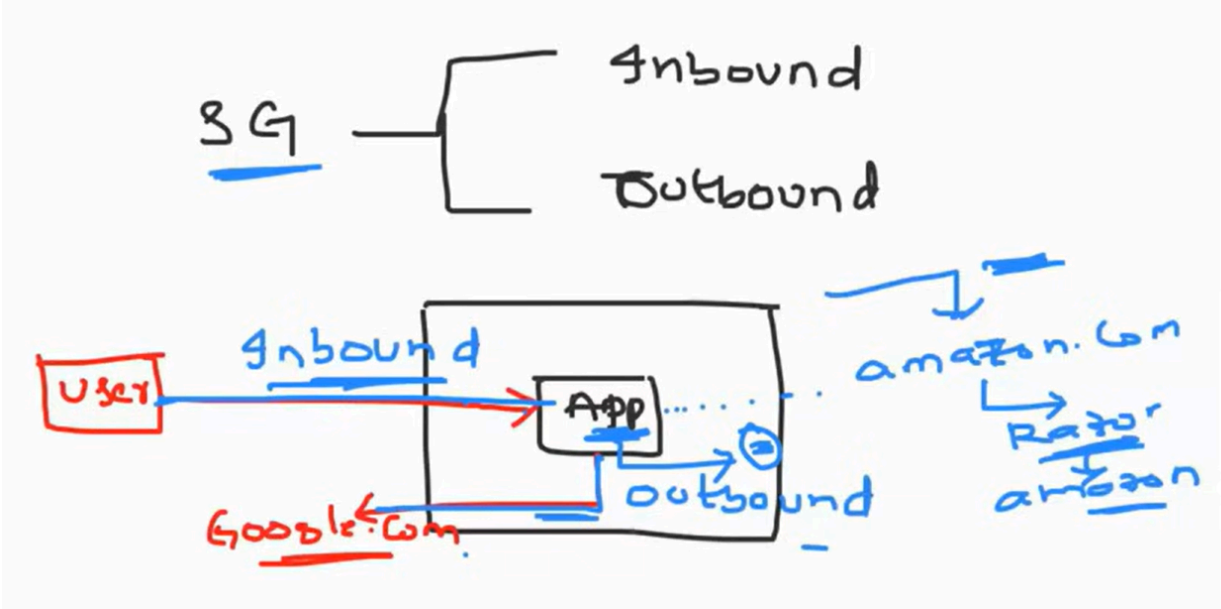
In AWS security is a shared responsibility.

SECURITY GROUP Vs NACL



1. The security group is at the instance level and by default AWS doesn't allow any traffic to the instance.
2. We should allow ports to let the traffic flow through those ports to the application.

INBOUND AND OUTBOUND TRAFFIC

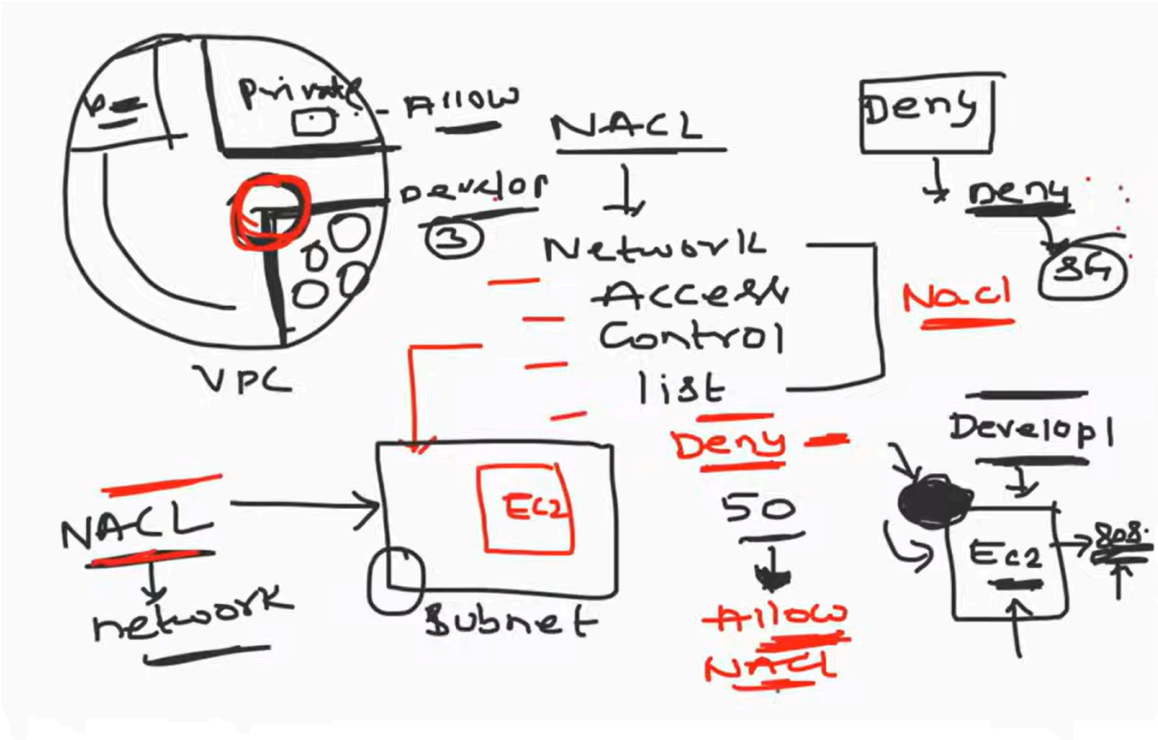


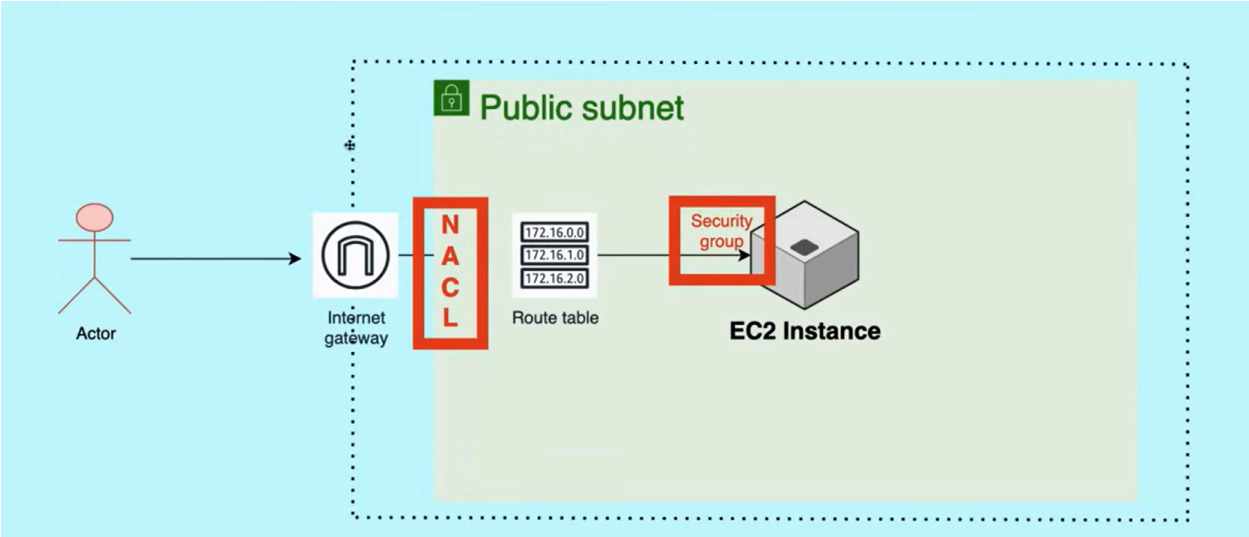
For inbound traffic - SG denies all by default
For outbound traffic - SG allows all by default

NACL

Network Access Control List

NACL is applied at subnet level - you can define what kind of traffic do you want to deny.





When you create a VPC AWS creates a IGW by default

1. Create custom VPC and provide ip range
2. AWS will create IGW and NACL, and route tables.
3. Now we will create EC2 , SG.
4.
