DAY 6

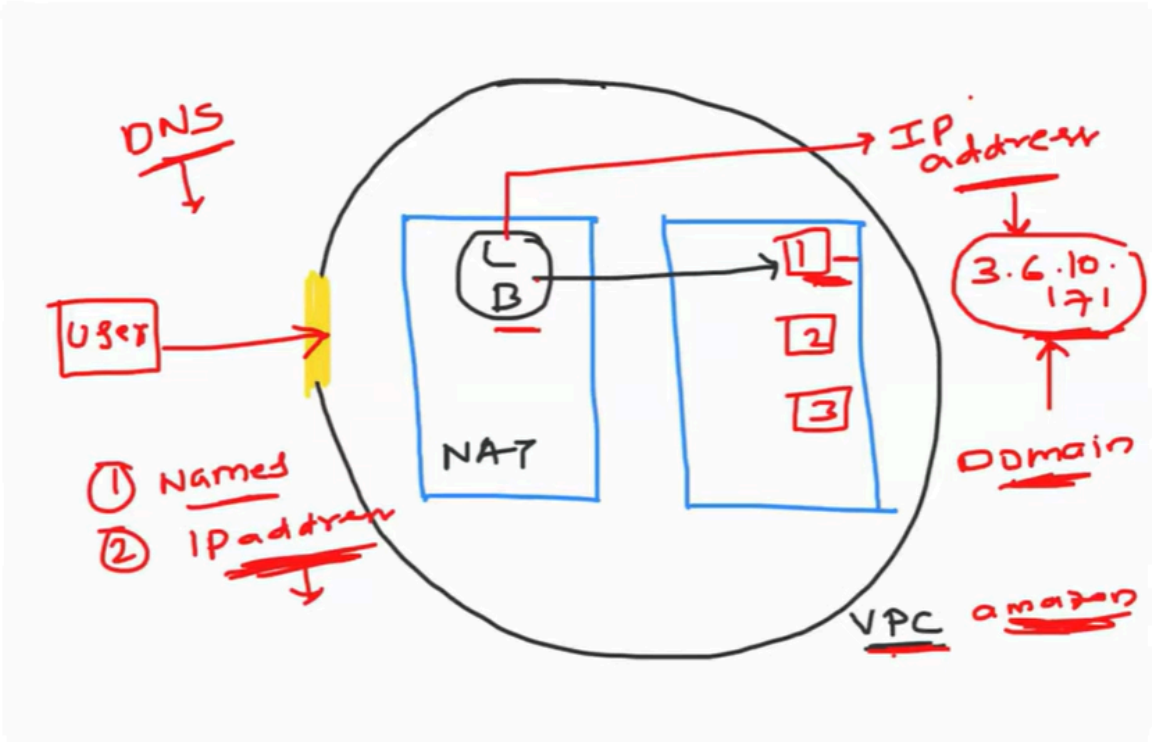
ROUTE 53

DNS- Domain Name System.

When we use any application like amazon.com, flipkart.com then indirectly you are using DNS. the application which ever is deployed they are assigned with ip address. You actually use domain names on the internet in real time to access applications.

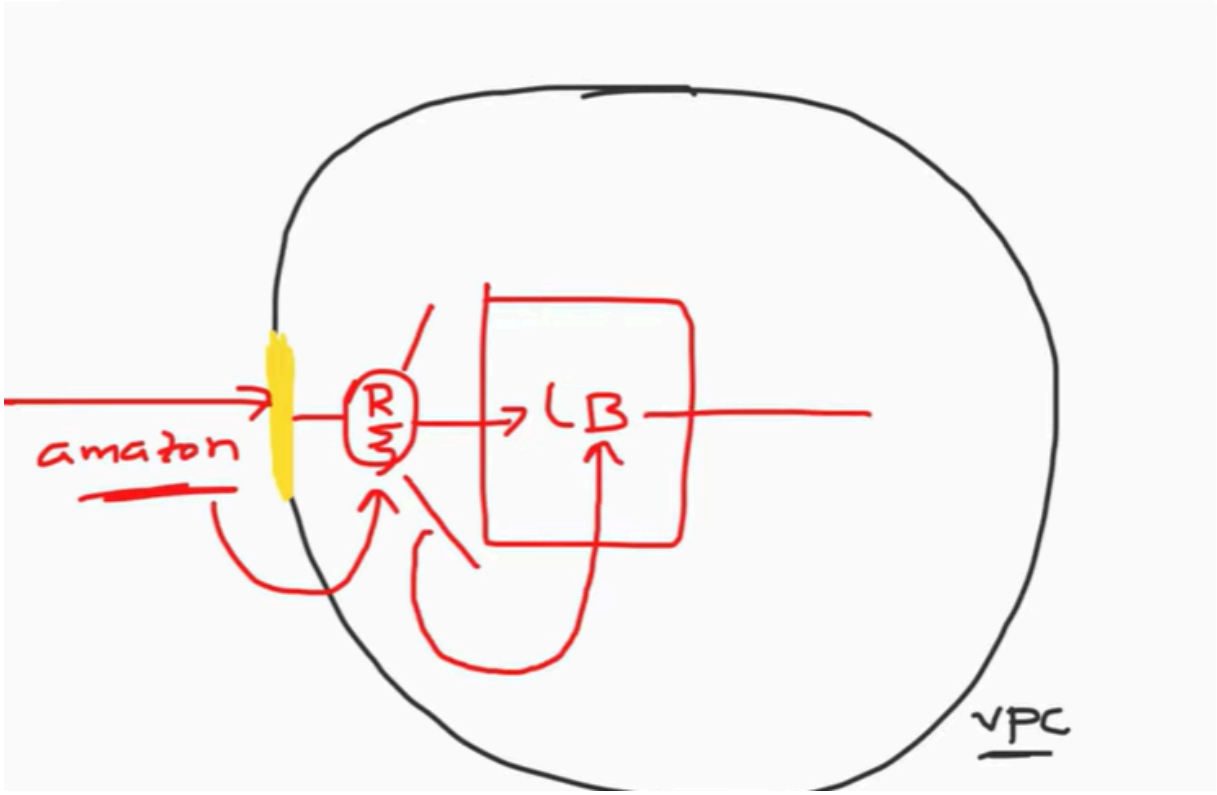
DNS converts that domain name to ip address.

Whether you create LB or application in AWS they get assigned with ip address.



DNS keeps records.

Route 53 is something like DNS service provided by AWS



1. Domain registration (AWS sells and also can integrate outside domain name)
2. Create Hosted zones.(where you create DNS records)
3. User→ resolves and checks mapping in hosted zones → load balancer.
4. Route 53 also supports health checks. On the web servers or applications. When the application is hosted or different servers, it can send requests periodically and see if it is active or not?
5. Request goes to hosted zones and route 53 looks for DNS records and if it is there it will resolve to ip address.

6.
