# AWS ZERO TO HERO

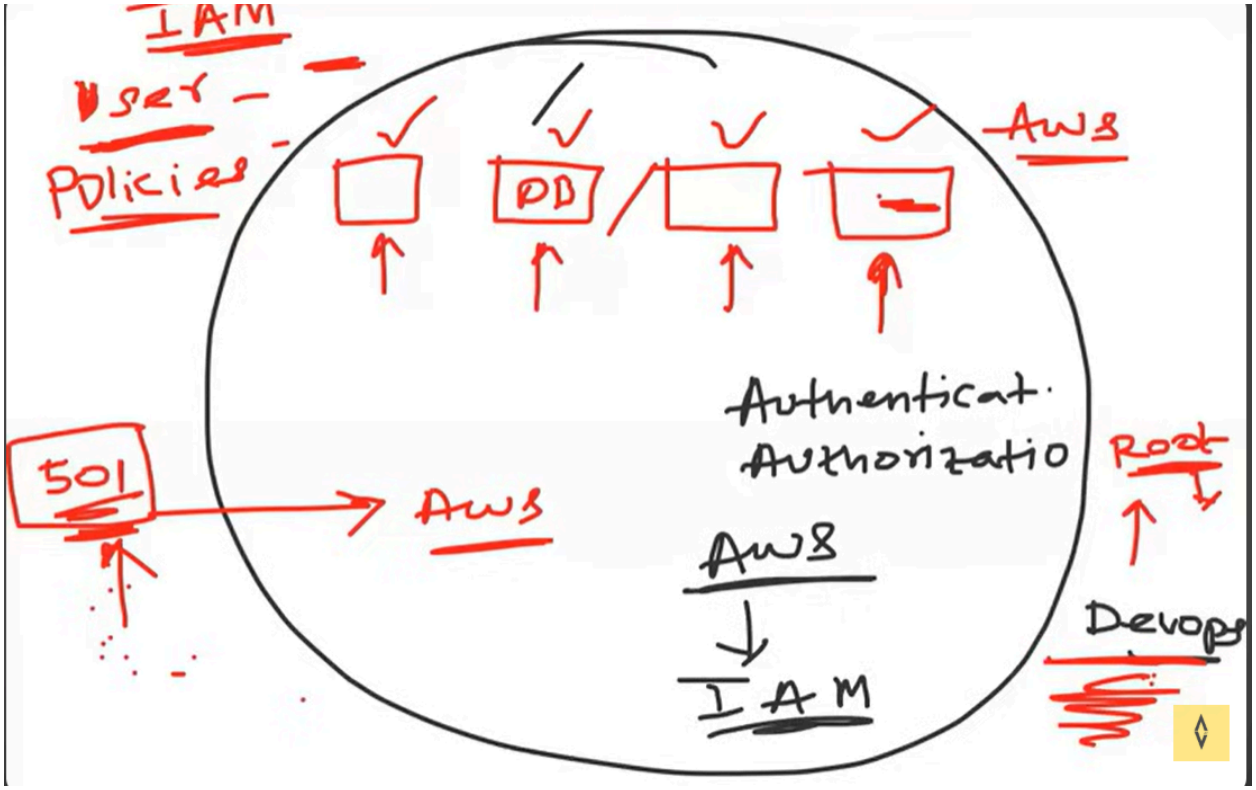
## DAY 2

## IAM

IAM - Identity and Access Management.
It talks all about authentication and authorization.

Authentication: Authentication basically means whether you are able to get access or not!
Authorization: Authorization is nothing but what kind of access you have.

For example, if you don’t have this authorization and authentication root access i.e, admin access will be given to every one in the company, they can go and delete some production data bases, which is very dangerous.



Here Understand the above example Some owner has root access for AWS account, and we have a lot of services inside the AWS account such as EC2, DB,  when user 501 requested access for DB, this owner creates a user in IAM for 501 and we have policies which will be attached to users.(like ReadOnly Access, admin access).
So after providing these details, users will be able to access DB!

Here the user in IAM is authentication and Policies are like authorization!

GROUPS: Groups is where you add multiple users in it who need the same access.
ROLES: Roles are where you will have username and password(which are temporary) when they need access to AWS services, Mostly used for communication between AWS accounts.
